

Graphics

# Computer Graphics vs. Graphic Design

- Computer Graphics is not using Photoshop- it's learning how to MAKE Photoshop.
- Within CS, computer graphics is the study of how to make a computer render images.
- We usually focus on 3D images, but it also encompasses 2D image processing.
- It involves a lot of code, and a lot of math (particularly geometry and matrix algebra), but the rewards are worth it.

# Some applications of graphics

- Cinematic CG
- Animation & Scientific Modeling
- Video games
- Photorealistic image rendering
- Image editing tools
- Java Applets

PHOTOSHOP RESOURCES

# Java Applets / Applications

- Most of the really cool stuff you can do with Graphics requires a very solid background
- One of the more basic forms of graphics that you can do is in Java applets and applications.
- Many times when writing an applet, you'll want to include graphics or animations that the user can interact with (such as an interactive chess game)

# Java's Graphics Package

- If you've never programmed in Java before, don't worry about it! We've provided and explained all the commands that you will need to know for this project.
- Ignore most of the code- All of the code that you add to draw the graphics will be placed in the paint method.

# Your objective

# The coordinate system

- When you specify where to draw an element, you are telling the computer the pixel locations of where you want to put the shape.
- The upper left hand corner is the origin, (0,0).
- The x axis increases as you go across
- The y axis increases as you go down.

increasing y

# startX and startY

- For your convenience, we included the startX and startY variables to serve as an easier reference point for you to use.
- So instead of going through the trouble to specify the exact pixel coordinates, you can just say startX+\_\_\_ and startY+\_\_\_\_\_
- Both have been initialized to 250. Feel free to change these or not use them at all.

# `g.setColor(Color.BLACK);`

- Use this command whenever you want to change colors. The next items you draw will be in that color until you change the color again.
- If you wanted to change the color to blue, you would type `g.setColor(Color.BLUE);`
- Or for red, `g.setColor(Color.RED);`
- And so on. Note that the name of the color must be in all capitals

# g.fillOval

- Draws an oval (or circle) and colors it in.
- **FORMAT:** `g.fillOval(xposition, yposition, width, height)`. All in units of pixels.
- A circle is just an oval where `width = height`
- **Sample:** `g.fillOval(startX+5, startY+5, 30 ,30);`

# g.fillArc

- Draws and colors in an arc. Think of a pie chart
- **FORMAT:**
- `g.fillArc(xposition, yposition, width, height, startAngle, arcAngle)`
- `startAngle` = the beginning angle
- `arcAngle` = the extent of the arc, relative to the beginning angle.

# If you finish early...

Feel free to add to your picture or even make a new one!

There are many more Java graphics tools you can use.

This site lists and explains all of them.
